

STAYOS

The accommodation marketplace built around the complete stay — not just the booking.

Investor Presentation — September 2026

Forward-looking discussion draft. The public-V1 state shown here represents the intended product after the current build program is completed; development is still in progress.

StayOS is building a full accommodation marketplace for guests, hosts and operators.

The product thesis is simple: make the entire stay — discovery, booking, payment, arrival, communication, checkout and reputation — feel like one coherent product.

2-sided

Guest + Host marketplace

End-to-end

Booking → Stay lifecycle

Mobile-first

Guest & Host execution

Web-ready

Guest / Host / Operations

Why it matters

- Accommodation marketplaces win on trust, availability, operational reliability and the quality of the stay — not on a listing screen alone.
- StayOS is being built as a complete operating product: domain rules drive the apps, APIs, automation, notifications and host workflows.
- The target is parity with the approved reference product model while keeping StayOS-specific architecture, data, branding and commercial decisions.

The real product starts after the user presses Book.

Discovery is only the entry point. The difficult part is delivering a reliable lifecycle across guests, hosts and the platform.

Uncertainty around availability, payment status, cancellation, arrival instructions and who to contact.	Listings, calendar, reservations, guests, messages, payouts and exceptions need one operating flow.	Broken lifecycle states create support cost, trust loss, cancellation risk and weaker repeat usage.

StayOS thesis

Own the complete stay lifecycle. Discovery gets the user in; operational excellence keeps the experience trustworthy.

One platform. Two sides. One continuous stay lifecycle.

StayOS is organized around the accommodation journey rather than isolated features.

DISCOVER	DECIDE	BOOK	PAY	ARRIVE	STAY	CHECK OUT	REVIEW
Search Map / filters	Listing Availability	Reservation Rules	Payment status	Arrival guide Access	Messages Support	Checkout Completion	Review Reputation

Guest: Home → Search → Listing → Booking → Payment → Trips → Arrival → Messaging → Stay → Checkout → Review.

Host: Today → Calendar → Listings → Reservations → Messages → Earnings → Profile → Co-host operations.

A guest should never feel that the booking ended at checkout.

The public V1 is designed around progressive disclosure: the right information at the right stage, while keeping the full stay accessible.

- Search with destination, dates, guests and practical filters.
- Rich listing details with pricing, availability, amenities, rules and host context.
- Clear booking and payment states rather than ambiguous pending states.
- Trip detail as the operational center: property, host, arrival information, check-in/out and actions.
- Reservation-linked messaging with automated lifecycle communication.
- Transparent cancellation and refund behavior under approved StayOS policy.
- Post-stay review and reputation lifecycle.

Trip Single source of stay truth	48h* Arrival-information release model	AR + EN Bilingual experience	End-to-end Lifecycle state management
--	--	--	---

*Current default implementation; final public policy remains subject to approved product/legal decisions.

Hosts get an operating system — not a listing form.

The host side is designed to manage the business behind every reservation.

TO DO	CALENDAR	LISTINGS	MESSAGES	ACCOUNT
Upcoming attention	Availability & pricing	Content & photos	Guests & automation	Profile & co-hosts
Reservation detail	Rules & booking settings	Readiness	Reservation threads	Permissions

- Granular co-host permissions with server-side authorization.
- Listing readiness, editor, photos, availability and reservation management.
- Reservation-linked messaging and scheduled lifecycle communication.
- Earnings and operational views built around the live bookings + payments path.

Trust is a system, not a badge.

Payment state, cancellation, evidence, arrival information, messaging and reputation are treated as connected operational domains.

BOOKING	PAYMENT	CANCELLATION	ARRIVAL	SUPPORT
State + rules	Status + proof	Policy engine	Timed information	Exceptions
Idempotent actions	Deadline enforcement	Refund treatment	Check-in/out	Admin controls

Implemented foundation

- Cancellation/refund lifecycle with approved V1 policy tiers and fee treatment.
- Payment deadline enforcement and payment-proof rejection lifecycle.
- Check-in / checkout lifecycle with time-gated arrival information.
- Reservation-linked messaging, notifications and scheduled automations.
- Host operating system and listing-management foundation.

A marketplace revenue model with room to expand.

The core V1 model is transaction-led: StayOS facilitates accommodation bookings and monetizes the transaction while hosts receive their eligible payout.

Guest	Host	StayOS
Books accommodation and pays the final booking amount under published checkout rules.	Supplies accommodation, manages availability and receives payout under applicable fee rules.	Earns platform/service economics from successful accommodation transactions.

Future expansion

- Higher-value host tooling and operational services.
- Additional hospitality-related services after the accommodation core is stable.
- Adjacent travel services only after the core marketplace reaches product maturity.

Investor note: no unsupported revenue, valuation or traction figures are presented as facts. Unit economics should be modeled from validated launch pricing, take rate, acquisition cost and supply data.

Compete on completeness, trust and operational depth.

The strategic benchmark is the behavior and depth of leading accommodation marketplaces — not a superficial visual copy.

Dimension	StayOS target
Discovery	Fast, visual, filterable accommodation search
Conversion	Clear listing → pricing → booking → payment flow
Trust	Transparent lifecycle, rules, evidence and reputation
Stay experience	Arrival information, messaging, check-in/out and support
Host operations	Calendar, listings, reservations, messages, earnings and permissions
Platform	Mobile-first product with Guest Web, Host Web and internal operations

Built as a real product, not a prototype stitched together.

The current architecture combines domain services, APIs, database migrations, client applications, automation and governance.

- Backend domain architecture with explicit services, repositories, schemas and authorization.
- Mobile application with live API integration and role-aware guest/host navigation.
- Web application for guest, host and internal operations where appropriate.
- Celery/Redis automation for lifecycle tasks and notifications.
- OpenAPI-driven client contracts and generated types.
- Automated testing and CI gates; the current merged baseline maintains an 80%+ backend coverage gate.

Internal planning visualization — not audited commercial traction.

The objective is a usable public V1 — not an endless feature backlog.

Execution is domain-by-domain: select a confirmed gap from the approved benchmark, build the complete coherent capability, validate it, merge it, then move to the next gap.

Indicative planning estimate: approximately 8–10 weeks from the current product state to a controlled public V1, assuming remaining core domains can be completed without major commercial/legal blockers. This is an estimate, not a committed launch date.

Public V1 is ready when the core marketplace works as one product.

Guest	Host	Platform
Discover and compare	Create/manage listings	Reliable APIs
Book and pay	Calendar & availability	Authorization
Manage a trip	Reservations & guests	Notifications
Communicate	Messages & automation	Background jobs
Arrive / stay / checkout	Earnings & permissions	Admin / support
Review	Co-host operations	Observability & safety

Launch philosophy

A smaller, reliable accommodation marketplace is more valuable than a large collection of half-finished features. The first public release should feel coherent, trustworthy and operationally complete.

What investment would accelerate

- Completion of the remaining core parity domains required for public V1.
- Supply acquisition and host onboarding operations.
- Guest acquisition and launch-market testing.
- Payment and operational infrastructure hardening.
- Support, trust & safety, and marketplace operations.
- Measured experimentation after launch: conversion, booking success, cancellation, repeat use and host retention.

Core V1

Accommodation first

2-sided

Network effects

Data-driven

Post-launch optimization

Expandable

Adjacent hospitality services

What we are NOT claiming yet

- No public-scale booking traction is claimed in this presentation.
- No unsupported market-size, revenue or valuation figures are presented as facts.
- The product remains under active development; the deck presents the intended public-V1 state.

STAYOS

Build the stay. Own the experience.

Confidential investor discussion draft — September 2026

Prepared from the current StayOS product direction, approved reference benchmark, implemented product baseline and current execution plan. Forward-looking estimates are explicitly labeled as estimates.
